# What does Census have to say?

# What does ESRI have to say?

## Stoplight approach based on Coefficient of Variation

The reliability is based on thresholds that Esri has established based on the usability of the estimates. Users should be aware that these are generalized thresholds:

-  High Reliability: Small CVs (less than or equal to 12 percent) are flagged green to indicate that the sampling error is small relative to the estimate, and the estimate is reasonably reliable.<sup>5</sup>
-  Medium Reliability: Estimates with CVs between 12 and 40 are flagged yellow—use with caution.
-  Low Reliability: Large CVs (over 40 percent) are flagged red to indicate that the sampling error is large relative to the estimate. The estimate is considered very unreliable.

<http://www.esri.com/library/whitepapers/pdfs/the-american-community-survey.pdf>

Coefficient of Variation is the Standard Error as a Percentage of the Estimate

$$CV = \frac{\left( \frac{MOE}{1.645} \right)}{ESTIMATE} \times 100$$

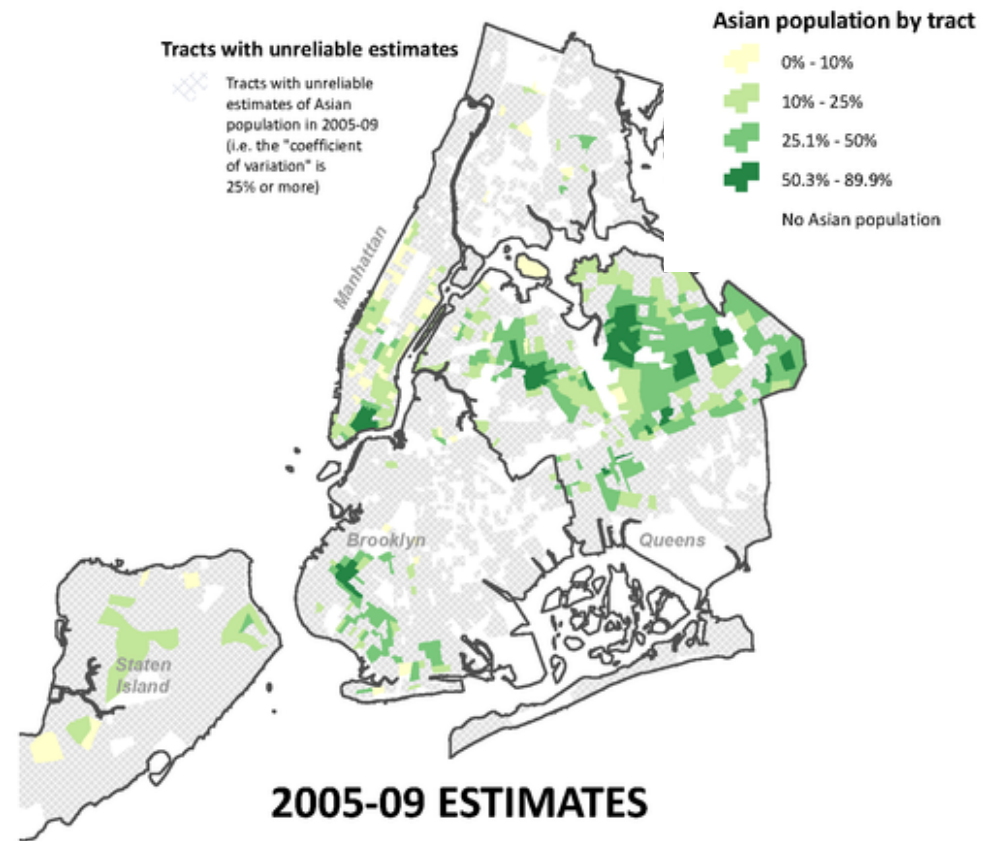

Geography	Poverty Estimate	MOE	Standard Error	CV	Interpretation
Tract A	40%	+/- 3%	1.8%	5%	Very Reliable
Tract B	4%	+/- 3%	1.8%	46%	Not Reliable

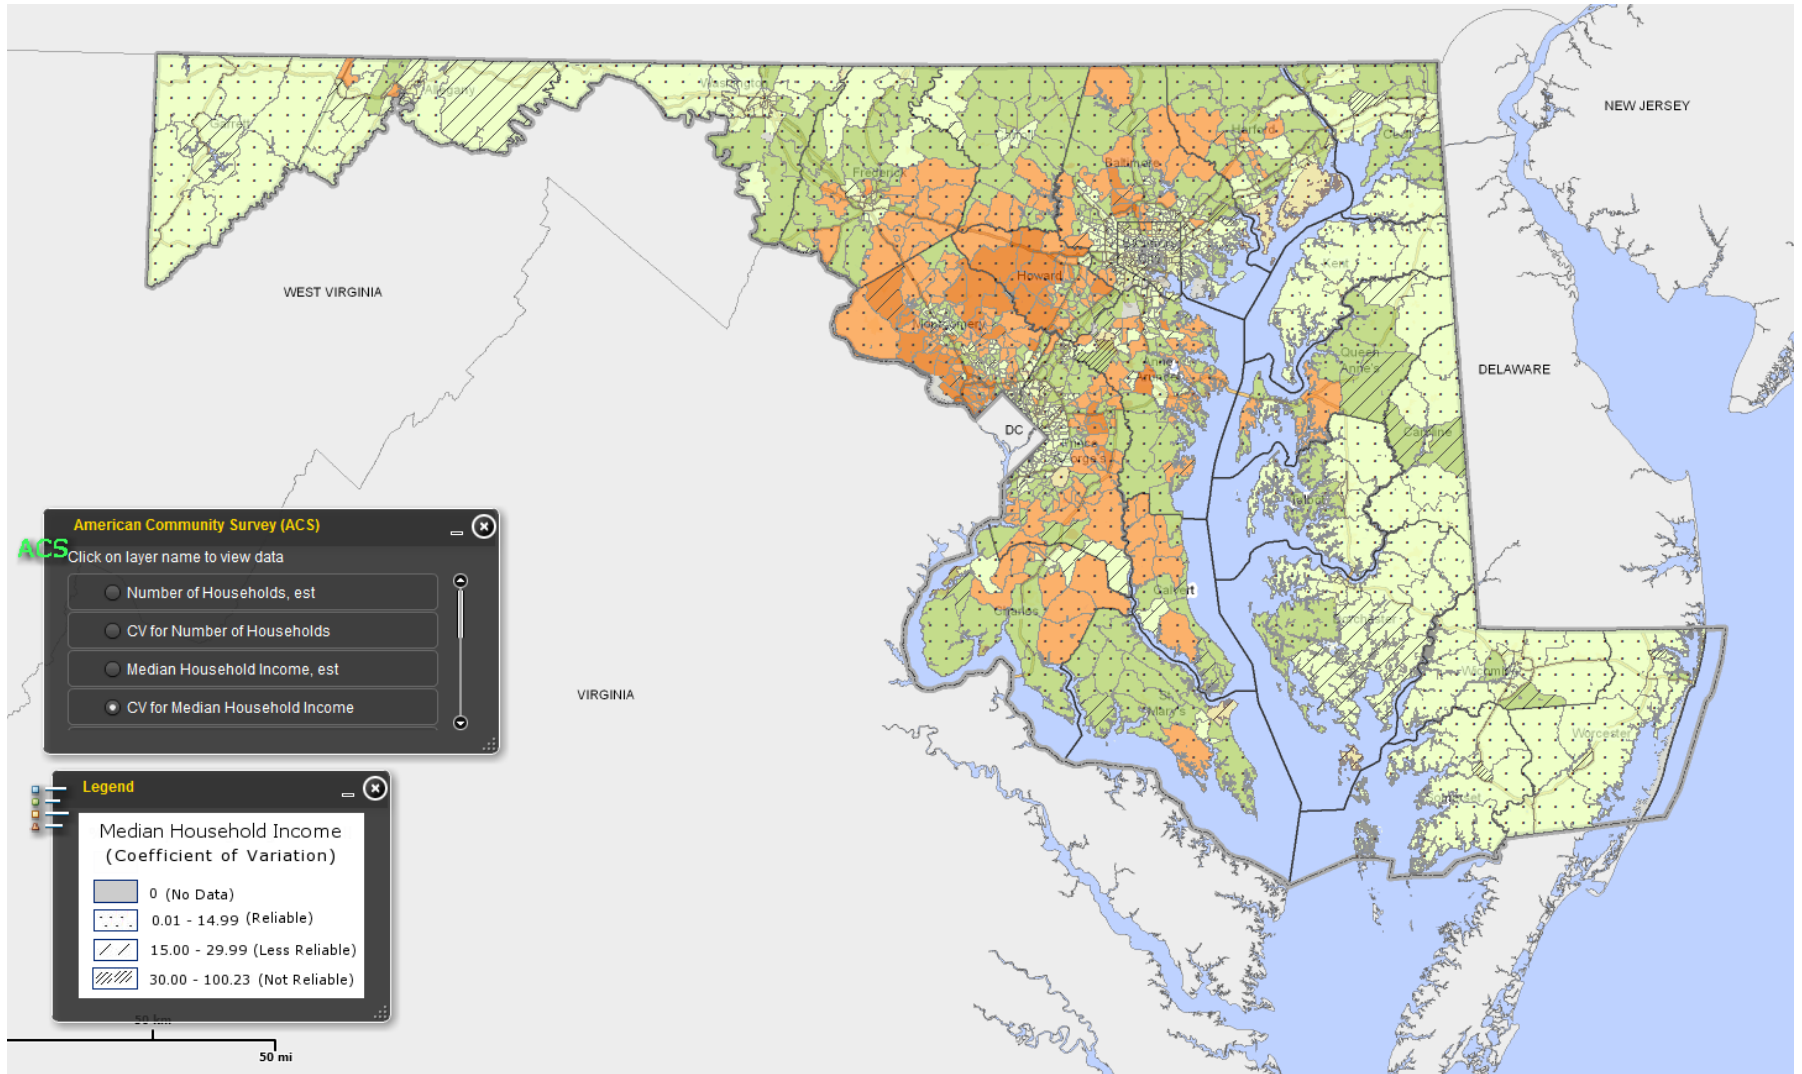

Is the *Coefficient of Variation* a good indicator of reliability?
